## **Acknowledgements**

First and foremost, my deepest gratitude to my reader, Professor Oana Tocoian, for not only her academic expertise, but her above and beyond support, time, and patience (especially patience). From teaching freshman year Microeconomics to writing my post-grad fellowship recommendations, Professor Tocoian has shaped my experience as an economics major at CMC in the most formative of ways. Thank you to my Research Methods professor, Yong Kim, for more guidance and patience; I am still not sure how you managed to keep an entire class, not just one thesis advisee, accountable. And of course, infinite gratitude to my family and friends: endless thank yous to Mom, Dad, my apartment-mates, Poppa lab buddies, and Thesis Surge pals for the moral support.

## **Abstract**

Using data from the Global Entrepreneurship Monitor, this paper examines differences in entrepreneurial perceptions (fear of failure, opportunity perception, self-efficacy, public opinion) between CEE and non-CEE countries, before and after the 2008 recession, as well as the effects of these perceptions on entrepreneurial motivation and overall levels of activity. The results suggest that CEE countries have systematically more pessimistic outlooks in terms of fear of failure and opportunity perception, but no difference from non-CEE countries in self-efficacy and public opinion. Additionally, most of the difference in fear of failure and opportunity perception, along with an increase in necessity-motivated entrepreneurship, comes after the recession, suggesting less durability and resilience of optimistic entrepreneurial perceptions in CEE countries. Finally, there is evidence of a higher threshold for a perceived opportunity to become a business reality in these post-socialist CEE countries.

# I. Introduction

A recent New York Times article laments the increasing division between Western and Eastern Europe in the European Union, this time marked by the victory of the anti-establishment party, Ano, in the Czech Republic. Whereas the Visegrad Group<sup>1</sup> “once stood as a beacon for post-Communist integration, ...today it symbolizes the failure of the West to completely integrate Central and Eastern Europe” (Bittner 2017). Bittner blames both Western Europe for treating its Eastern counterpart like “second-class citizens,” as well as CEE’s “lack of cultural preparedness for the new competitiveness” in the EU due to communism’s legacy of immense distrust. He points to CEE’s failure, perhaps not by fault but by nature, to change the culture and mindset of its people: “while liberalizing their economies, they have forgotten to liberalize their minds.” This last criticism may extend beyond politics into the state of entrepreneurial motivations in the post-socialist transition economies of CEE as well. Whereas transition is formally considered complete in terms of formal economic infrastructure from command to market economies, have the informal institutions that motivate entrepreneurship changed sufficiently? Are entrepreneurial perceptions and motivations the same in the post-socialist CEE countries as they are in the West? Or is there evidence to believe that they are behind in terms of “cultural preparedness,” to put it in Bittner’s language?

While entrepreneurial actions and outcomes have been studied extensively, motivations and perceptions surrounding entrepreneurship have been subject to significantly less scholarship, particularly in a cross-country or regional comparison

---

<sup>1</sup> Czech Republic, Poland, Slovakia, and Hungary, all of which joined the EU in 2004.

context. Most of the literature on entrepreneurship in post-socialist countries focuses on the most visible levels of transition regarding entrepreneurship policy and infrastructure, as well as their effect on entrepreneurial activity and outcomes. Research on entrepreneurial motivations tends to be in the space of leadership psychology, which assumes that entrepreneurs are largely innately motivated, using cross sectional data that ignores cultural contexts that may change over time. However, it makes sense to study motivations and perceptions at the country level and across years because there are significant differences and changes in the country-level annual Global Entrepreneurship Monitor reports<sup>2</sup> and, presumably, what differs between countries is culture and shared history<sup>3</sup>.

I seek to fill these gaps by examining the differences in entrepreneurial perceptions between CEE countries and non-CEE countries, and then the effects of these perceptions on entrepreneurial motivation and overall levels of activity. I find that CEE countries<sup>4</sup> do differ significantly from non-CEE countries in fear of failure and opportunity perception with more pessimistic outlooks, but not in self-efficacy or public opinion of entrepreneurs. Moreover, CEE countries respond differently to the 2008 recession with a greater and longer lasting increase in fear of failure and decrease in opportunity perception, as well as an increase in necessity rather than opportunity entrepreneurship. I also find that, while the nature of entrepreneurship in CEE countries differs in terms of lower overall levels of

---

<sup>2</sup> <http://www.gemconsortium.org/report>

<sup>3</sup> And, of course, development level, access to resources, economic conditions, etc., but let us say that those are encompassed by “shared history.”

<sup>4</sup> I am interested in CEE countries, including the Baltic states, because they are widely considered the “beacon of post-communist integration,” in Bittner’s terms. Central and Eastern Europe integrated market economy infrastructure relatively rapidly and smoothly compared to other formerly communist countries, where many still lack structural institutions (or were in the mid-2000s; see Table 1 of EBRD Transition Indicators) and suffered a prolonged turnaround time from economic decline to growth in the post-transition period throughout the 1990s.

entrepreneurship and more necessity-motivated entrepreneurship, entrepreneurial perceptions, save opportunity perception, do not have a differential effect on entrepreneurial activity in CEE countries. There is evidence of a higher threshold for opportunity perception, even in cases of necessity entrepreneurship, for one to be an entrepreneur in a CEE country.

Although the Berlin Wall fell over 25 years ago, and although most barriers<sup>5</sup> at the time of formal transition in the 1990s no longer exist today, it is possible that a cultural legacy of communism persists in the entrepreneurial ecosystem. The rest of the paper explores this possibility by proceeding as follows: Section II discusses the existing literature, Sections III and IV examine the data and empirical strategy, Section V analyses the results, and finally, Section VI presents the conclusions.

## II. Literature Review

### A. Entrepreneurship in Post-Socialist Economic Transition

There were two principal schools of thought regarding economic transition: 1) reform should take place gradually and cautiously in order to mitigate side effects as much as possible and 2) it is best to cut our losses through an immediate and expedient liberalization of prices and privatization of state firms. Whereas China and Vietnam, for example, belong to the former camp, much of Eastern Europe followed the latter. The reasoning is that although private ownership is not a sufficient condition to ensure the efficient operation of a market economy, it is a prerequisite (Dana 2005). Many reformers

---

<sup>5</sup> E.g. legal insecurity, political instability, lack of financial resources.

also drew from the ideas of Schumpeter (1934) and Kirzner (1973), believing that the creation of numerous new firms would be the principal mechanism whereby heavily industrialized planning structures would be transformed into a market system for allocating resources (Estrin and Mickiewicz 2010). However, the reforms of the early 1990s concentrated on stabilization and privatization of existing firms rather than supporting new ones, and Aidis, Estrin, and Mickiewicz (2008) show that entrepreneurship levels were lower in transition economies as a group than in other developed and developing economies.

Szerb and Trumbull (2016) continue this analysis of entrepreneurship in post-socialist countries into the 2000s and most recent decade. Their results imply that transition is over and that these post-socialist countries (except Russia) are on a normal capitalist path, with any differences being attributable to different levels of economic development rather than having a fundamentally different economic system. My own analysis of EBRD transition indicators confirms these results of the completion of transition in terms of formal institutions; transition indicators for CEE countries have remained for the most part unchanged since 2003<sup>6</sup>. However, Szerb and Trumbull also point out that some “informal” characteristics among the former socialist countries likely stem from their shared socialist heritage, for example low levels of opportunity perception and cultural support. Thus, rather than homogeneous entrepreneurship support policies, they posit that effective policies in CEE should fit the particular entrepreneurial inhibitors of the targeted territory.

Informal institutions like norms and values are as important as formal institutions in shaping economic behavior and attitudes. Sztompka (1996)<sup>7</sup> argues that communism left

---

<sup>6</sup> See EBRD transition indicators table in appendix.

<sup>7</sup> As cited in Minniti 2013.

a legacy of norms, which he calls a “bloc culture,” that are not conducive to entrepreneurship: priority of dependence over self-reliance, conformity over individualism, and rigidity and extremism over tolerance and innovation. Generalized trust is another value that is lacking in transition economies, confirmed by the World Value Surveys reported by Howard (2000)<sup>8</sup>, which affects expectations and risk-taking. Informal institutions may even have a longer lasting effect than formal ones because of their generational transfer.

The distinctiveness of the transition context has led some authors to question the form in which entrepreneurship is manifested. Scase (1997) separates entrepreneurship from proprietorship: he defines entrepreneurship as a person’s commitment to capital accumulation and business growth, while proprietorship is a prioritization of the ownership of property and other assets, which may be used to realize profits but are not used for longer term capital accumulation. He emphasizes that proprietors are more likely to consume any surplus rather than reinvest in their business, and that proprietors account for the majority of small business owners in transition economies because individuals are stimulated by the desire for protection from the uncertainties of emerging markets, the thirst for personal autonomy, and out of economic necessity.

The literature on post-Socialist transition economies also draws a distinction between the countries of Central and Eastern Europe (CEE) and those of the former Soviet Union (FSU). CEE economies largely inherited a stronger legal, institutional, and cultural framework for successful entrepreneurship, partly because many CEE countries had

---

<sup>8</sup> As cited in Minniti 2013.

thriving capitalist economies in the nineteenth century and interwar period, and also because of CEE countries' accession to the European Union (Estrin et al. 2009).

## B. Necessity versus Opportunity Entrepreneurship

An early attempt to define opportunity as opposed to necessity entrepreneurship was undertaken by the Global Entrepreneurship Monitor (GEM) when it began its global surveys in 1999. GEM asks, “Are you involved in this start-up to take advantage of a business opportunity or because you have no better choices for work?” However, because this definition is subjective and generally unavailable in other datasets, Fairlie and Fossen (2017) set out to create an operational definition of necessity versus opportunity entrepreneurship using data readily available most economic datasets. They propose using initial unemployment status as a proxy for entrepreneurial motivation: individuals who are initially unemployed before starting businesses are defined as “necessity” entrepreneurs, and individuals who are wage/salary workers, enrolled in school or college, or are not actively seeking a job are defined as “opportunity” entrepreneurs. With one of the most important puzzles in entrepreneurship literature being the apparent counter-cyclical of business creation, as Bögenhold and Staber (1990)<sup>9</sup> demonstrated a positive correlation between self-employment and unemployment across OECD countries, Fairlie and Fossen find that “opportunity” entrepreneurship is pro-cyclical and “necessity” entrepreneurship is countercyclical. Since necessity entrepreneurship is thought of as business creation in the face of limited alternative opportunities, this implies that the entrepreneur’s wage-earning income is low. Given the downward wage rigidity in the labor market, the main

---

<sup>9</sup> As cited in Fairlie and Fossen 2017.

cause of low earnings in the wage and salary sector will more likely be through unemployment rather than a reduction in wages, so it makes sense to associate unemployment with necessity entrepreneurship. Fairlie and Fossen also show that “opportunity” entrepreneurship is associated with the creation of more growth-oriented businesses.

Several other studies have also used business motivations to construct taxonomies of entrepreneurs. Some theorists talk about the distinction in terms of push and pull motivations: push motives tend to play more of a role for unemployed founders, pull motives for employed ones (Hinz and Jungbauer-Gans 1999)<sup>10</sup>. Expected job loss was one of the priority motives for unemployed founders, whereas employed founders tended to emphasize personal independence. Scase’s (1997) distinction between entrepreneurship and proprietorship is also analogous to the opportunity-necessity distinction. In even earlier literature, Cooper and Dunkelberg (1986)<sup>11</sup> differentiate between the craftsman-entrepreneur and manager-entrepreneur, where the former has a goal of self-realization and the latter concentrates on monetary and growth aims.

Ultimately, one of the goals of constructing these motivation taxonomies is to better predict entrepreneurial outcomes in order to drive policy that encourages entrepreneurs to be the types that are more likely to succeed or drive economic growth. GEM reports indicate that opportunity entrepreneurship is correlated with higher growth, more innovative and niche-focused ventures, and a higher export-orientation (Reynolds et al. 2002). In German GEM reports, opportunity entrepreneurs are said to have higher rates of survival and are characterized as “good entrepreneurship,” or the type that will contribute

---

<sup>10</sup> As cited in Smallbone and Welter 2003.

<sup>11</sup> As cited in Smallbone and Welter 2003.

to national economic development in the long run (Bergmann and Sternberg 2007). Necessity entrepreneurship is then viewed as a negative determinant of national growth and development.

Smallbone and Welter (2003) examine the meaning and appropriateness of concepts of necessity and opportunity-driven entrepreneurship in early stage transition economies where market reform has been slow, so countries like Russia, Ukraine, and Belarus rather than Central and East European countries, where market reform is more advanced. Using survey data and case studies, they conclude that the main weakness of the dichotomous concepts of necessity and opportunity motivations is that expectations change over time as individuals learn, their capabilities change, and external conditions change. Particularly in the command-to-market transition context, economic necessity is undoubtedly a factor, and few people become entrepreneurs to respond to an identified market opportunity, although immediate push factors like unemployment are not dominant either. Rather, motivations operate at different times and levels, from deep-seated antecedent influences, to immediate triggers, to external conditions and personal circumstances that cause the terms “opportunity” and “choice” to be interpreted differently given the context. Moreover, low prevalence of high growth or “productive” entrepreneurship may be due more to institutional deficiencies rather than individual entrepreneurial motivations.

With these many ways of categorizing entrepreneurial motivations and criticisms of the prevailing classification in mind, I ultimately still use GEM’s opportunity-necessity definition of motive in my analysis<sup>12</sup>. But, I do take into account the nuances of these

---

<sup>12</sup> Mostly because of data limitations, as I did not have access to *initial* employment status or detailed case studies of individual respondents.

definitions and criticisms, incorporating current work status into my interpretations and the way I code my opportunity entrepreneurship indicator<sup>13</sup>.

## C. Entrepreneurial Perceptions

Van der Zwan et al. (2016) examine the determinants of being a necessity versus an opportunity entrepreneur, tying the motivation taxonomy to entrepreneurial perceptions. While their study finds socio-economic differences—opportunity entrepreneurs tend to be male, younger, wealthier, more proactive, and more optimistic—they do not find significant differences in entrepreneurial perceptions and other personality traits as determinants of entrepreneurial motivation. My contribution to this line of literature is to examine these characteristics in a country context to identify the cultural legacy effects; while there may not be universal personality and perception differences, there may be cultural context-specific ones.

The effect of natural disasters on entrepreneurial actions and perceptions is studied by Monllor and Altay (2016). They find that natural disasters have a positive impact on entrepreneurial opportunity perceptions and actions, but not on perceptions of self-efficacy, fear of failure, or entrepreneurial intentions. They take these results as evidence of Schumpeter's creative destruction theory, viewing natural disasters as disruptive processes that create an environment ripe for innovation and entrepreneurship. Results show a higher perception of entrepreneurial opportunity and more entrepreneurial action, specifically opportunity-motivated entrepreneurial activity, reaffirming that this increase is not out of necessity or constraint. Although I am not looking at natural disasters specifically, Monllor

---

<sup>13</sup> See OPP2 in variable descriptions in the appendix.

and Altay's analysis of entrepreneurial perceptions in response to an unpredictable, exogenous event may be relevant because a recession can also be seen as such an event. However, my analysis of CEE countries produces the opposite results, likely because Monllor and Altay only use pre-recession data from 2000 to 2007, and natural disasters tend to be locally confined whereas the Great Recession was felt globally.

The novel contribution of this paper is to explore the intersection of these three sections: the post-socialist context, the opportunity-necessity motive distinction, and entrepreneurial perceptions as socio-cultural determinants.

### III. Data Description

I primarily rely on data from the Global Entrepreneurship Monitor (GEM) dataset to examine the relationships among entrepreneurial motivation, perception, country, and changes over time. The GEM Adult Population Survey (APS) measures attitudes toward entrepreneurship and prevalence of startup activity and business ownership in over 80 countries from the general population of both entrepreneurs and non-entrepreneurs, with at least 2000 respondents per represented country per year surveyed. Surveys are conducted annually, but not consistently for every country (not every country has data for each year, and they are not conducted at regular intervals). The goal of GEM's APS is to explore the role of the individual in the lifecycle of the entrepreneurial process, collecting data on socio-economic characteristics of populations as well as subjective perceptions of the entrepreneurial environment.

This paper uses GEM data from the years 2003 through 2013 (the most recent and complete data that include the CEE countries of interest). By aggregating the years 2003

through 2013, my dataset includes over 1.5 million observations<sup>14</sup> from the general population, of which approximately 100,000 are entrepreneurs. Other datasets used include The World Bank's Doing Business Data, which evaluates the ease with which individuals can start and operate a business in each country using a ranking system, and the European Bank for Reconstruction and Development's (EBRD) Transition Report. Summary statistics are shown in Table 1, a country-level breakdown of summary statistics in Table 2, and variable descriptions in the appendix.

## Caveats of the Data

While entrepreneurship research has increased in specificity over recent years, its definition and conception and still very broad, although there has been consensus about its multidimensionality (Wennekers & Thurik 1999; Acs & Audretsch 2010)<sup>15</sup>. Szerb and Trumbull point out that GEM's total early-stage entrepreneurial activity index (TEA), which measures the prevalence of entrepreneurship, "equates a Silicon Valley entrepreneur with a new Ugandan shepherd or with a recently opened grocery shop in Thailand." For this reason, I attempt to distinguish between different types of entrepreneurs by their entrepreneurial motive in order to add an additional degree of specificity to the analysis on entrepreneurship in a transition country context.

Fear of failure and entrepreneurial motivation are both fairly subjective, nebulous concepts. GEM attempts to define these using the questions, "would fear of failure inhibit you from starting a business?" which assumes a hypothetical scenario, and "are you

---

<sup>14</sup> I should note that this data is **not** a panel dataset at the individual level; respondents in each country are not the same across years. At the country level, however, this data can function as an (unbalanced) panel by taking country-year averages.

<sup>15</sup> As cited in Szerb and Trumbull 2016.

involved in this start-up to take advantage of a business opportunity or because you have no better choices for work?” to assign a binary definition to each of fear of failure and entrepreneurial motivation. Critics point out the obvious subjectivity of these definitions, and that an individual’s answer may depend on the success of the business launch instead of pre-launch motivations or different language interpretations of the concepts of failure and necessity.

While the GEM dataset is robust, it is so expansive that it would be very difficult to administer centrally the same number of surveys for every country in every consecutive year, so each country has a team that handles the data collection on its own. This means that in a given year, there may be 40,000 observations for one country, 2,000 for several others, and zero for the rest; and this is inconsistent across years.

## IV. Methodology

Because of the unbalanced time series nature of this data where only some countries are represented in some years, I am concerned about countries being consistently represented over time, especially when examining changes in time related to the recession. Since some countries are only represented in one or two years, it does not make sense to look at time trends for those countries, and they may potentially skew the data for particular years in which particular countries are overrepresented. Thus, I drop the countries that only appear in three or fewer years. The CEE countries represented in my refined dataset are: Hungary, Romania, Poland, Latvia, Croatia, and Slovenia (6 out of the 12 CEE countries). To make sure that this selection process does not skew my variables of interest in favor of more developed countries where accessibility of conducting representative surveys may be

greater, I compare the summary statistics of the original dataset to my reduced dataset in Table 2. It is worth noting that the overall averages of the reduced dataset do differ slightly from those of the original data: most dropped countries were African, South American, Asian, and Middle Eastern countries<sup>16</sup>; and the remaining countries have lower levels of entrepreneurship overall and less optimistic entrepreneurial perceptions<sup>17</sup>. This means that my reduced sample looks more like CEE countries, which may mean that differences could be understated.

The number of observations per country per year also presents an inconsistency problem. Most countries have around 2000 observations in a given year<sup>18</sup>, but some countries, like the UK, have absurdly high numbers of observations in some years (e.g. 43,000 observations in 2006). I am concerned about the overrepresentation of these (Western and highly developed countries like the UK, Spain, and Switzerland), so I introduce weights in my analysis so that each country has approximately the same weight in any given year, and I also use cluster analysis by country.

Most of the variables I work with are binary indicators. Questions were asked as yes or no questions to individual respondents, so I coded “don’t know” or “refuse to answer” observations as missing. My variables of interest that indicate entrepreneurial perceptions were presented as self-assessment statements that respondents could choose to agree or disagree with: fear of failure (“fear of failure would prevent you from starting a new business,” coded as fearfail), opportunity perception (“in the next 6 months, there will

---

<sup>16</sup> In that order of most dropped.

<sup>17</sup> Looking back at the dropped African and South American countries, they do have substantially higher levels of entrepreneurship and optimistic perceptions. I do wonder how much this is due to skewed survey methodology (since most were one-off surveys) and different interpretations of entrepreneurship?

<sup>18</sup> And I cleaned the data so that none have fewer than 1600 observations in any given year.

be good opportunities to start a business,” coded as *opport*), self-efficacy (“you have the knowledge and skills to start a new business,” coded as *suskill*), and public opinion of entrepreneurs<sup>19</sup>.

Variables of interest that indicate entrepreneurial activity are: total entrepreneurial activity (is the individual currently a nascent entrepreneur? Coded as *tea*) and opportunity motivated entrepreneurship (“are you involved in this startup to take advantage of a business opportunity or because you have no better choices for work?” Coded as *teaopp*)<sup>20</sup>. Other independent variables include country, a binary indicator for CEE<sup>21</sup>, year, and a binary indicator for post-recession years. Depending on the particular specification model, I control for gender, age, education, work status, and income. I also include country-year fixed effects when I am not interested in time-varying effects to control for general macroeconomic conditions that vary by country, by year.

The first question I ask is: do entrepreneurial perceptions and activity differ for CEE countries? I regress the CEE indicator on fear of failure, opportunity perception, self-efficacy, public opinion, TEA, and opportunity-motivated entrepreneurship with the following controls:

$$y_{ict} = \alpha + \beta_1 * CEE_c + \beta_2 * Year_t + \beta_3 * Educ_i + \beta_4 * Female_i + \beta_5 * Age_i + \beta_6 * Age_i^2 + \beta_7 * Work_i + \beta_8 * Income_i + \varepsilon_i \quad (\text{Model A})$$

---

<sup>19</sup> This last public opinion entrepreneurial perception indicator is actually derived from three separate questions (“in your country, most people consider starting a new business a desirable career choice,” “in your country, those successful at starting a new business have a high level of status and respect,” “in your country, you will often see stories in the public media about successful new businesses”) that seem to measure the same sentiment and trended very similarly across countries and time, so I simply use the first question (coded as *nbgoodc*) to represent public opinion of entrepreneurs in general.

<sup>20</sup> See end of variable descriptions table for different versions of *teaopp*.

<sup>21</sup> I did also look at the country coefficients to confirm that individual CEE countries behaved similarly, not just one or two countries driving these effects.

Then, if CEE countries do have a systematically more pessimistic outlook in entrepreneurial perceptions from the model above, I ask if CEE countries are also less resilient in perceptions in the face of hardship. Does the 2008 recession have a differential effect on entrepreneurial perceptions in CEE countries? I interact the recession indicator with the CEE indicator as shown in the following equation:

$$y_{ict} = \alpha + \beta_1 * CEE_c + \beta_2 * PostRec_t + \beta_3 * CEE_c * PostRec_t + \beta_4 * Educ_i + \beta_5 * Female_i + \beta_6 * Age_i + \beta_7 * Work_i + \beta_8 * Income_i + \varepsilon_i \quad (\text{Model B})^{22}$$

where y takes on the values of fear of failure, opportunity perception, self-efficacy, public opinion, TEA, and opportunity-motivated entrepreneurship.

The purpose of examining entrepreneurial perceptions is not just for its own sake, but because we assume that entrepreneurial perceptions (fear of failure, opportunity perception, and self-efficacy) actually affect entrepreneurial actions (total entrepreneurial activity and opportunity-motivated entrepreneurship). For this reason, I run a fundamental assumptions check to confirm that this is true with the following equation:

$$y_{ict} = \alpha + \beta_1 * FearFail_c + \beta_2 * Opport_c + \beta_3 * Suskill_c + \beta_4 * Educ_i + \beta_5 * Female_i + \beta_6 * Age_i + \beta_7 * Country_c * Year_t + \varepsilon_i \quad (\text{Model C})$$

where y is tea and teaopp. I control for the usual individual level controls except work status and income because those are highly correlated with tea and teaopp, and I use country-year fixed effects to absorb macroeconomic conditions.

Finally, after establishing that entrepreneurial perceptions do in fact affect entrepreneurial activity, I ask whether these perceptions have a differential effect on

---

<sup>22</sup> For all following regressions, I leave out Age<sup>2</sup> because it does not change the results by much.

activity for CEE countries. I use the following equation that simply adds CEE interaction terms with each of the entrepreneurial perception indicators to Model C:

$$y_{ict} = \alpha + \beta_1 * \text{FearFail}_c + \beta_2 * \text{Opport}_c + \beta_3 * \text{Suskill}_c + \beta_4 * \text{Educ}_i + \beta_5 * \text{Female}_i + \beta_6 * \text{Age}_i + \beta_7 * \text{Country}_c * \text{Year}_t + \beta_8 * \text{FearFail}_c * \text{CEE}_c + \beta_9 * \text{Opport}_c * \text{CEE}_c + \beta_{10} * \text{Suskill}_c * \text{CEE}_c + \varepsilon_i$$

(Model D)

## V. Results and Discussion

### A. Entrepreneurial Perceptions and Activity

The regression results for Model A are summarized in Table 3. With high degrees of significance, fear of failure and opportunity perception do differ for CEE countries. Being in a CEE country increases the likelihood of fear of failure preventing someone from starting a business by 5%, significant with a p-value of 0.02. Fear of failure can also be interpreted as risk aversion, so those in CEE countries are on average more risk averse. The controls in this first regression in Column 1 also make sense: being female increases risk aversion, being retired or in school reduces risk aversion because presumably the pressure to maintain a stable income is off, and being in the top third of the income distribution also reduces risk aversion because one likely has some degree of a financial cushion. There does not seem to be an obvious correlation, however, between education level and risk aversion.

Being in a CEE country decreases the likelihood of a perceived business opportunity by 14%, and this is especially significant with a p-value of 0.001. The time fixed effects seem consistent with 2008 recession trends: opportunity perception increases

from 2003-2007, reaches a maximum, drops in 2008-2009, and slowly recovers thereafter. Being female and being of older age both reduce opportunity perception because these demographic groups do have more constrained access to opportunities. Being unemployed has the most negative effect on opportunity perception, and being a student or retired also has a negative effect compared to employed respondents who presumably see the most opportunities as active members of the workforce.

However, the CEE indicator is insignificant for self-efficacy (skill self-perception) and public opinion of entrepreneurs (nbgoodc, nbstatus, nbmedia)<sup>23</sup>. There does not appear to be a measurable difference in how entrepreneurs are perceived and how qualified people feel to be entrepreneurs in CEE countries<sup>24, 25</sup>. This might be explained by the idea of an external locus of control as part of Communism's legacy: less optimistic perceptions in CEE countries may not be due to individual ownership of problems in the entrepreneurial ecosystem (i.e. "I have lower relative skills"), but a generalized lack of agency due to the external environment (e.g. fear of failure, lack of opportunity). Figure 1 illustrates the relative average self-efficacy compared to relative opportunity perception by country, and we can observe that CEE countries are grouped approximately in the middle for average self-efficacy, whereas they are grouped on the lower end of opportunity perception.

The controls for self-efficacy and public opinion are significant in ways that make sense intuitively, so there is further reason to believe the insignificance of the CEE

---

<sup>23</sup> Although I only list nbgoodc in Table 4 because all of the nb\* variables produce approximately the same results.

<sup>24</sup> I also tested if there are differences along gender or other dimensions (i.e. CEE interacted with female, etc.), and there are no significant differences with these specifications either.

<sup>25</sup> Again, as a sanity check, the controls make sense: females have lower self-perceived skill, unemployed and retired/students have lower self-perceived skill, and higher income has greater likelihood to perceive skill. Although, one would think that a higher level of education is correlated with more skill perception, and it turns out that work status and income absorb most of this effect, which is only significant for grad school (more likely to perceive skill) when I tested this without work status and income.

indicator is not just due to noise. Male, older, working, and wealthier respondents are more likely to believe they have the skills to start a business<sup>26</sup>. Older and more highly educated respondents are less likely to think their country views entrepreneurship as a desirable career choice, which makes sense because opportunity cost is much higher for these demographics, and they are more likely to operate in social circles with more traditional or conventional notions of success. Those who are not working (unemployed and retired/student categories) are slightly more likely to view entrepreneurship as desirable, again because they have a lower opportunity cost of becoming an entrepreneur<sup>27</sup>.

Columns 5 and 6 show that one is significantly less likely to be an entrepreneur or choose opportunity entrepreneurship in CEE countries, which is consistent with the literature on the lower overall levels of entrepreneurship and higher prevalence of necessity entrepreneurship in these countries (Scase 1997; Aidis, Estrin, and Mickiewicz 2008; Szerb and Trumbull 2016).

## B. Entrepreneurial Perceptions, Activity, and Post-Recession Time Trends

Given the overall more pessimistic outlook of CEE countries in entrepreneurial perceptions from the subsection above, are there time trends that drive shifts in these pessimistic attitudes? The results summarized in Table 4.1 show that the 2008 recession does seem to have a differential effect on entrepreneurial perceptions in CEE countries,

---

<sup>26</sup> Interestingly enough, education is not significantly correlated with self-efficacy in these results. One would think that they would be positively correlated, but it could be that the reference group changes as education increases, so people perceive their own skills relative to the people around them.

<sup>27</sup> Also interestingly, whereas females have much lower self-efficacy on average, there is no significant difference in their view of public opinion of entrepreneurs. Entrepreneurship is just as desirable and externally validated for females, but they feel like they do not have the requisite personal ability; females appear to view themselves differently than they do public perceptions.

which may be evidence that entrepreneurship is less enduring and resilient in times of economic hardship in CEE countries.

Column 1 shows that fear of failure increases significantly for all countries post-recession, but to a much greater degree for CEE countries. For other countries, fear of failure increases by 5% post-recession; for CEE countries, almost 15%—the effect for CEE countries is almost three times as large as it is for other countries. In Column 2, opportunity perception also has a differential effect for CEE countries, as it is significantly lower in CEE post-recession. It appears that most of the significant difference in opportunity perception and fear of failure is due to the post-recession difference for CEE countries, with pre-recession CEE having no significant differences. Self-efficacy (Column 3) drops after the recession for non-CEE countries, but it does not seem to have a measurable effect in CEE countries, reaffirming the external locus of control hypothesis from the previous section. Whereas economic hardships due to the recession seem to be internalized in other countries as a personal failure of lacking skill, CEE countries seem to blame lacking external opportunities.

Figure 2 highlights these time trends for opportunity perception and fear of failure for CEE countries. Opportunity perception seems to increase for countries in CEE in 2005 after the Visegrad Group joined the European Union in 2004, and then it drops drastically in 2008-2009 after the recession. There is a much greater shock to opportunity perception in CEE countries on average, and they have not yet recovered to 2007 levels of optimism about business opportunities, whereas non-CEE countries returned to 2007 levels by 2010. Fear of failure has also increased drastically since 2008 for CEE countries, whereas the

increase is much slighter for non-CEE countries. This suggests that there may be less “resilience” in optimism regarding entrepreneurship in these countries.

Post-recession years also have a positive effect on entrepreneurship for all countries, and to a significantly greater degree for CEE countries as seen in Table 4.2. This is an added nuance to existing literature that merely warns us of lower levels of entrepreneurship in CEE countries—actually, the negative effect of the CEE indicator on entrepreneurship seems to be mostly pre-recession. Rates of entrepreneurship for CEE and non-CEE countries are converging over time, with less of a differential post-recession, as evidenced in Figure 3. But, it seems like most of that increase in entrepreneurship in CEE countries is necessity-motivated rather than opportunity-motivated entrepreneurship, as the interaction term between the CEE and post-recession indicators has a negative effect on opportunity entrepreneurship. Figure 4 visually depicts this as well; whereas the share of both necessity and opportunity entrepreneurs in CEE countries increases over time, necessity entrepreneurship increases much more drastically. This fits in with Fairlie and Fossen’s findings that necessity entrepreneurship increases after an economic downturn, whereas opportunity is associated with expansions.

## C. Effect of Entrepreneurial Perceptions on Entrepreneurial Activity

The results of Model C’s regression in Table 5 confirm that perceptions do matter for entrepreneurial actions. Column 1 in Table 5 indicates that self-efficacy (suskill) has the strongest effect on total entrepreneurial activity and is the greatest determinant in this model by a substantial margin (coefficient of 0.12), followed by opportunity perception (coefficient of 0.06), and then fear of failure (coefficient of -0.03), all of which are hugely

significant. Once again as a sanity check, the controls behave as we expect them to: college and beyond makes a person more likely to be an entrepreneur, whereas female and older age make someone less likely to be an entrepreneur.

In Column 4, we examine the opportunity versus necessity entrepreneurship distinction. Looking only at the subset of entrepreneurs, this specification follows the previous literature in attempting to distinguish differing characteristics between necessity and opportunity entrepreneurs; it should not be interpreted as the effect of certain entrepreneurial perceptions on an individual's choice to pursue opportunity or necessity-motivated entrepreneurship (presumably because they do not have a choice if it is necessity-motivated). This model looks within entrepreneurs to determine who is a willing entrepreneur and who is merely out of luck in the labor market. It appears that all of the explanatory variables affect opportunity entrepreneurship in the same way that they do total entrepreneurial activity: those with lower fear of failure, higher opportunity perception, and higher self-efficacy are more likely to be willing entrepreneurs. Opportunity perception is the greatest determinant here (with a coefficient of 0.07), which seems obvious given the shared "opportunity" in the variable names. What is interesting to note, however, is that self-efficacy (coefficient of 0.05) is a much smaller determinant of opportunity entrepreneurship—this suggests that necessity entrepreneurs need a substantial degree of self-efficacy as well, as it is not particularly unique to opportunity entrepreneurship but remains the largest determinant of entrepreneurship overall.

Finally, after having established that entrepreneurial perceptions do actually affect entrepreneurial activity and motivations, and that there may be policy implications especially since the shift in perceptions is largely post-recession, I examine the differential

effect on activity for CEE countries in Model D. The regression results produced in Column 1 of Table 6 show a significantly negative interaction term between the CEE indicator and opportunity perception, which suggests that the presence of a perceived opportunity in CEE countries is less likely to be associated with overall entrepreneurship than in non-CEE countries. In context, this has a rational interpretation: given higher conditions of constraint and lower levels of trust in post-socialist countries, there is a higher threshold for a perceived opportunity to become a business reality. Fear of failure and self-efficacy do not seem to be differential in terms of how they impact overall entrepreneurship.

In Column 2, while that same interaction effect between CEE and opportunity perception is not significant for opportunity-motivated entrepreneurship, the interaction term between CEE and suskill is, which means that self-efficacy is less likely to be associated with opportunity entrepreneurship in CEE countries than non-CEE countries. This higher threshold for self-efficacy for opportunity entrepreneurs again makes sense because, with “tougher” conditions, one must be more confident in one’s own skills to survive in the entrepreneurial environment. Column 3 shows us that self-efficacy actually has a positive differential effect for necessity entrepreneurship in CEE countries, meaning that those with higher self-efficacy are more likely to be necessity entrepreneurs in CEE countries, which again reaffirms the higher prevalence of necessity entrepreneurship in these countries.

The fourth specification in Column 4 that looks only at the subset of entrepreneurs, as noted above, is not causal. Given that you already are an entrepreneur, you do not get to choose whether it is by necessity or opportunity, so entrepreneurial perceptions here again do not have a causal effect on entrepreneurial motivation. But, simply looking at

distinctions between necessity and opportunity-motivated entrepreneurship, this does seem to indicate that opportunity-motivation in CEE countries is even more correlated with lower fear of failure, substantially greater opportunity perception, but lower skill self-perception than in non-CEE countries, although the link between suskill and teaopp is still not negative because the coefficient on the interaction term is not enough to overturn the suskill coefficient.

## VI. Conclusion

The findings of this paper can be summarized as follows: 1) CEE countries have more pessimistic entrepreneurial perceptions, and these differences are driven by post-recession effects, 2) CEE countries have lower levels of entrepreneurship and share of opportunity-motivated entrepreneurship (relative to necessity entrepreneurship), 3) entrepreneurial perceptions do in fact affect entrepreneurial actions and motivations, and 4) opportunity perception has a diminished positive effect on entrepreneurial activity in CEE countries, suggesting a higher threshold for a perceived opportunity to become a business reality in these countries.

These results do evidence, although they cannot prove (as there are infinitely many other factors at play), the cultural legacy of Communism. Despite the formal and prompt transitions to market economies, accession to the European Union, and presence of legal, financial, and educational institutions supportive of entrepreneurship in these post-socialist countries, the generational transfer of informal institutions like norms and values seem to be inescapable. A generalized lack of trust and external locus of control are plausible lingering sentiments because of the lower levels of risk-tolerance and opportunity

perception compared to ordinary levels of self-efficacy and public opinion of entrepreneurs in CEE countries.

The policy implications are substantial, particularly because of the post-recession trends. If there is indeed less resilience during economic shocks in CEE countries as shown by the dominating increase in negative entrepreneurial perceptions and necessity-motivated entrepreneurship, increased entrepreneurial support during economic downturns rather than a one-size-fits-all strategy may be more effective. Entrepreneurial education does not seem to be significantly lacking in CEE countries, evidenced by the lack of difference in self-skill perception between CEE and non-CEE countries, but there could be a benefit to teaching the importance of failure (in order to normalize it) and opportunity recognition, not just skills to succeed.

The opportunities for future research in this area are plenty. To put more of an international relations context<sup>28</sup> into this economics paper, I will look more closely at some of the macro-level political factors that I touched on in the introduction and incorporate indicators for those into the analysis. The increasingly conservative political climate in countries like Hungary and the Czech Republic sets up what some would argue to be a hostile environment for entrepreneurship. One could also incorporate World Bank data on economic development levels (or speed of development, GDP growth, etc.) into a country-level analysis to see how countries at similar levels of development compare in their entrepreneurial perceptions and activity. Looking at “non-CEE” countries with more specificity would also add depth to this analysis: how does CEE compare to the rest of the

---

<sup>28</sup> Which I intend to do next semester, in the spring of 2018, for a research fellowship from the Keck Center for International and Strategic Studies at CMC.

EU? All Western countries? Other formerly communist-countries like the former Soviet Union and Asian countries?

To take this analysis a step further, one could also examine not just entrepreneurial perceptions, which affect entrepreneurial activity, but also entrepreneurial outcomes. Are there differences in firm performance or dropout rates? The share of “gazelles”<sup>29</sup> or high-impact entrepreneurs?

I also hope to supplement this data-driven analysis with fieldwork and case studies<sup>30</sup>. More qualitative data could shed light on the “why” behind the conclusions from this paper, as well as what these differences look like in practice for entrepreneurs in Eastern Europe. Because qualitative data requires much more context for understanding, it would make sense to zoom in on a particular country and its entrepreneurs and cultural history.

Figure 1. Graph of Self-Efficacy vs. Opportunity Perception

## Self Efficacy vs. Opportunity Perception

Average of Suskill vs. average of Opport. Color shows details about CEE. The marks are labeled by Country. Details are shown for Country.

Figure 2. Graph of Opportunity Perception and Fear of Failure over Time

### Average Opportunity Perception and Fear of Failure

The trends of average of Fearfail and average of Opport for Year broken down by CEE. The data is filtered on Country, which keeps 52 of 52 members.

Figure 3. Graph of CEE vs. Non-CEE TEA over Time

Entrepreneurship Time Trends

The trend of average of Tea for Year broken down by CEE.

Figure 4. Graph of Necessity vs. Opportunity Entrepreneurship in CEE over Time

Entrepreneurship Time Trends by Motivation for CEE Countries

The trends of average of teaopp and average of teanec for Year. The data is filtered on CEE, which keeps CEE.

## IX. Appendix

### EBRD Transition Indicators

## Important Variables and Descriptions

VARIABLE NAME	CODE	VARIABLE LABEL
COUNTRY		NUMERIC COUNTRY [PHONE] CODE
CEE	0	CEE COUNTRY INDICATOR
	1	Other country Country = Hungary, Romania, Poland, Latvia, Croatia, or Slovenia
YEAR		YEAR SURVEYED
POSTREC	0	POST-RECESSION YEAR INDICATOR
	1	Year = 2007 or earlier Year = 2008 or later
<b>Demographic control variables</b>		
INCOME	33 3467 68100	HOUSEHOLD INCOME: RECODED INTO THIRDS lowest 33% tile middle 33% tile upper 33%tile
EDUC	111 1212 1316 1720	HIGHEST EDUCATIONAL ATTAINMENT up to some secondary education secondary degree post secondary graduate experience
WORK	10 20 30	GEM HARMONIZED WORK STATUS: 3 CATEGORIES working, full-time or part-time not working retired, students
FEMALE	0 1	RESPONDENT GENDER male female
AGE		RESPONDENT EXACT AGE
<b>Entrepreneurial perceptions (asked of general population)</b>		
OPPORT	0 1	In the next six months will there be good opportunities for starting a business in the area where you live? NO YES
SUSKILL	0 1	You have the knowledge, skill and experience required to start a new business? NO YES
FEARFAIL	0 1	Fear of failure would prevent you from starting a business? NO YES
NBGOODC	0	In your country, most people consider starting a new business a desirable career choice? NO

	1 YES
NBSTATUS	In your country, those successful at starting a new business have a high level of status and respect? 0 NO 1 YES
NBMEDIA	In your country, you will often see stories in the public media about successful new businesses? 0 NO 1 YES
<b>Entrepreneurial activity and motivations (asked only of entrepreneurs)</b>	
TEA	Identified as nascent entrepreneur or new business owner as part of Total Entrepreneurial Activity (TEA) 0 NO 1 YES
SUREASON/ OMREASON	Entrepreneurial motivation? TAKE ADVANTAGE OF BUSINESS OPPORTUNITY 2 NO BETTER CHOICE FOR WORK 3 COMBINATION OF BOTH OF THE ABOVE 4 HAVE A JOB BUT SEEK BETTER OPPORTUNITY
TEAOPP	(Recoded) entrepreneurial motivation, indicator for opportunity entrepreneur <sup>31</sup> 0 NECESSITY OR NON-ENTREPRENEUR 1 OPPORTUNITY ENTREPRENEUR
TEAOPP2	Entrepreneurial motivation among those who have a choice <sup>32</sup> NON-ENTREPRENEUR (but not unemployed; unemployed and necessity entrepreneurs are coded as missing) 0 1 OPPORTUNITY ENTREPRENEUR
TEANEC	Indicator for necessity entrepreneur 0 OPPORTUNITY OR NON-ENTREPRENEUR 1 NECESSITY ENTREPRENEUR

<sup>31</sup> Derived from SUREASON (startup reason) and OMREASON (owner-manager reason), both of which ask the respective respondent whether they started their business to take advantage of a business opportunity or had no better choice for work. TEAOPP = 1 if SUREASON/OMREASON = 1 and TEA = 1.

<sup>32</sup> I use TEAOPP2 when looking at the opportunity entrepreneurship as a choice relative to the general population sample, but I use TEAOPP when conditioning on being an entrepreneur (if TEA = 1) to act as a binary indicator of opportunity versus necessity entrepreneurship.
